

This FSPro run shows the projected fire probability over the next 7 days. The heat was the isolated heat signatures and scattered heat that is shown in the fire islands (Spot Fires) this IR was delivered on 09/14. The ERC's and winds are from the Flack Summit RAWs with 3 days of forecast weather. A barrier is placed around the south side of the fire where it is shown as contained.

This model shows an overall probability of less than 5% chance of any fire spread from the ignitions. This is in line with the higher fuel moistures from the last storm along with the forecast precipitation over the coming week.
